

1.3 Problem Statement

Phase 1 - Project Introduction | Implement Client Script & UI Policy (Incident)

1. Problem Description

In many service desks the Incident form is used with static behaviour: every field is always displayed in the same manner and no guidance is given to the agent as data is entered. Agents may therefore save incomplete records, for example a critical incident without an assignment group or an On Hold incident without a reason. Such records are hard to route, track and report on.

2. Issues Identified

- No warning or guidance is displayed when a critical (Priority 1) incident is created.
- Fields such as On hold reason are not enforced when the incident is placed on hold.
- Closed incidents can still be modified, which affects record integrity.
- The form shows unnecessary fields, causing confusion for new agents.
- Inconsistent data entry leads to poor reporting and delayed resolution.

3. Impact of the Problem

Area	Impact
Data quality	Incomplete or inconsistent incident records
Response time	Critical incidents may not get immediate attention
Reporting	Inaccurate metrics due to missing values
User experience	Cluttered form and lack of guidance for agents

4. Proposed Solution

Implement an onChange Client Script on the Priority field to alert the agent for critical incidents, and configure UI Policies on the Incident form to make fields mandatory, visible or read-only based on State and Priority. Together these enforce process discipline directly on the form and improve the quality of incident data.
