

6.2 Client Script and UI Policy Interaction

Phase 6 - Integration and Functional Validation | Implement Client Script & UI Policy (Incident)

1. Interaction Between the Components

Both components react to changes on the form, but they address different needs. The Client Script communicates with the agent by displaying messages, while UI Policies control the state of fields. As they do not modify the same property of the same field, they can be used together without conflict.

2. Interaction Scenarios

Scenario	Client Script	UI Policy	Combined Result
Priority set to 1 - Critical	Shows critical message	UP-02: Assignment group mandatory	Agent is warned and required to assign a group
Priority changed from 1 to 3	Clears message	UP-02 reversed	Form returns to normal behaviour
State set to On Hold	No action	UP-01 shows On hold reason as mandatory	Reason must be provided
State set to Closed	No action	UP-03 makes fields read-only	Record protected from edits
Form opened	Skipped (isLoading)	onLoad policies applied	Correct behaviour with no false message

3. Conflict Avoidance

- The Client Script does not change the mandatory, visible or read-only status of any field.
- UI Policies do not display messages, so there is no overlap of responsibility.
- The Client Script clears only its own message when the value is not critical.
- Execution order values are kept at default because there are no conflicting actions.

4. Best Practices Followed

Simple logic was preferred, UI Policies were used for field behaviour as recommended by ServiceNow, and the Client Script was limited to messaging. This keeps the solution easy to test and maintain.
